Abstract

An experiment was conducted to assess the performance of sweet pepper varieties as influenced by nitrogen levels from August 2014 to February 2015 at Mangalpur, Chitwan. The experiment was laid out in two factorial Randomized Complete Block Design (RCBD) with three replications having sixteen treatments. Varieties and levels of nitrogen significantly affected growth, yield and qualitative parameters of fruits. Hybrid Indra and NS 632 performed better than open pollinated varieties viz. Sagar and California Wonder. Days to fifty percent flowering of NS 632 were earlier than California Wonder. Indra variety had the highest plant height (52.18 cm), number of secondary branches per plant (13.51) from 250 kg N/ha through chemical fertilizer while number of leaves per plant was higher in NS 632 variety (57.22) than Sagar variety (47.37). Indra variety showed the highest fruit weight (87.59 g) and total yield (39.45 t/ha) but NS 632 variety produced more number of fruits per plant (9.25) than California Wonder variety. This study showed that sweet pepper yield of hybrid varieties applied with 250 kg N/ha through chemical fertilizer was appropriate dose to get optimum yield under Chitwan condition.

Keywords: : Sweet pepper and Nitrogen

Introduction

Sweet pepper (*Capsicum annum L.* var. *grossum* Sendt.; $2n=2x=24$) is commonly known as sweet pepper, capsicum or green pepper. In Nepal, sweet pepper is growing in 1318 ha area with production of 14216 mt and productivity of 10.8 t/ha (MoAD, 2014). Among capsicum growing areas of Nepal, Chitwan is the major Sweet pepper producing district with 114 ha area, 1362 mt production and productivity of 12 t/ha (MoAD, 2014). Nepal imports a huge amount of chilli and sweet peppers (2859587 kg) from India (MoAD, 2013).

Chilli cultivars greatly vary in ability to flowering, fruit set, yield potential and other quantitative attributes under different agro-climates (Rani, 1996 and Gupta, 2003). It is fact that, all varieties do not perform equally well in all areas. It is essential to know the performance of varieties in a specific area.

Capsicum requires heavy fertilization at early stage for optimum plant growth and higher yield. Nitrogen is an essential part of nucleic acids and chlorophyll molecules (Devlin, 1972). Use of organic manures alone cannot fulfill the crop nutrients requirement

(Deore, Limaye, Shinde & Laware, 2010). Bokhtiar, Paul, and Alam, (2008) reported that organic manures, when applied with chemical fertilizers gave better yield than individual ones. Therefore, use of the optimum level and combination of nutrients depend on the variety as well as location (Sharma & Upadhaya, 1993). Growers are still facing problems in the use of chemical fertilizers, particularly nitrogenous fertilizer, for optimum production.

Materials And Methods

Location of the sites

The experiment was conducted in the farmer's field of Mangalpur, Chitwan (27040' N, 84019' E), Central Development Region, Nepal. It has a subtropical climate with an altitude of 228 meters above mean sea level and soil is alluvial deposited by Narayani and Rapti River.

| Details | Mean | Ratings |
|---------------------|---------------------------------------|------------|
| pH | 6.7 | Acidic |
| Total nitrogen (%) | 0.13 | Medium |
| Phosphorous (kg/ha) | 104.6 | High |
| Potash (kg/ha) | 56.6 | Low |
| Organic matter (%) | 2.5 | –Medium |

Experimental details

The experiment was carried out from August, 2014 to March, 2015 with two factors factorial completely randomized block design (RCBD) with 16 treatment combinations and 3 replications. Four varieties (viz. California Wonder, Sagar, NS 632 and Indra) and four levels of N from different sources (viz. 200 kg N/ha through chemical fertilizer, 200 kg N/ha through FYM,

250 kg N/ha through chemical fertilizer and 150 kg N/ha through chemical fertilizer) were used. The individual plot size was 2.5 m × 2.4 m. The row to row distance was 50 cm and plant to plant distance was 40 cm. There were 5 rows in each plot and 6 plants per row. There were 30 plants in each plot and inner 6 plants were selected for taking observation. Thirty days old seedlings were transplanted on 22nd September, 2014.

The quantity of organic manure was calculated based on nitrogen content of the organic manure tested in the laboratory (Table 3). The amount of organic manures to fulfill the required nitrogen was doubled assuming that only 50% of N would be available in the first season (Baldwin and Greenfield, 2006; Bary, Cogger and Sullivan, 2004).

Well decomposed farmyard manure (FYM) was obtained from the farmer's shed. Farmyard manure was applied @ 30 t/ha in all plots. Treatments having 200 kg N/ha through FYM was applied plus 80 t/ha FYM in the plot. FYM was applied during third ploughing which is one week prior to planting of seedlings. Nitrogen was applied at the rate of 150, 200 and 250 kg/ha through Di-ammonium phosphate (DAP) and urea for the remaining treatments. The recommended dose of phosphorous (100 kg/ha) was applied through DAP (46% P₂O₅). In FYM treated plots, phosphorous was supplied through single super phosphate (16% P₂O₅). The recommended dose of potash (100 kg/ha) was applied through Muriate of Potash (MOP). In each treatment, half dose of nitrogen, full dose of phosphorous and potash were incorporated into the soil at the time of transplanting. The remaining amount of nitrogen was splitted into three equal parts and each part was top-dressed at 25, 50 and 75 days after transplanting.

Observations and measurements

Plant height

Plant height was measured from the ground level to the growing tip.

Number of leaves per plant

Number of green, photosynthetically active leaves excluding senescent and emerging leaves per plant were counted.

Number of primary and secondary branches per plant

Primary branches and secondary branches were counted on selected 6 plants at 60 and 100 days after transplanting.

Number of fruits per plant and Average fruit weight

Harvested fruits from 12 observational plants of each plot were taken. For calculating mean fruit weight (g), the total weight of the fruits was divided by the total number of fruits picked from 12 observational plants in cropping period. Total number of fruits taken from 12 observational plants was divided by 12 to calculate Number of fruits per plant.

Fruit yield

The fruit weight from all the pickings obtained from 12 observational plants of each treatment was summed up separately treatment wise and yield (t/ha) was calculated based on the area covered by 12 observational plants.

Results

Effects of varieties and nitrogen levels on growth parameters

There was significant effect of varieties on plant height at all growth stages of the plant. At all growth stages, the highest plant height was recorded in variety Indra. At 100 DAT, variety Indra was the tallest (52.18 cm) (Table 4).

There was significant increment in the plant height from increasing levels of nitrogen from 150 to 250 kg N/ha. At 100 DAT, the highest plant height (49.26 cm) was attained with 250 kg N/ha through chemical

fertilizer and the lowest (43.66 cm) from 200 kg N/ha through FYM. The effects of 150 kg N/ha through chemical fertilizer and 200 kg N/ha through FYM were non-significant.

At 100 DAT, the highest number of leaves was from NS 632 (57.22) which was at par with Indra (55.03). The lowest was recorded in Sagar (47.37) which was statistically similar to California Wonder (48.68). Also at 100 DAT, the highest number of leaves per plant (58.56) was obtained from 250 kg N/ha and the lowest (47.13) from 150 kg N/ha.

There were significant effect of varieties on plant height and number of secondary branches where as non-significant with number of primary branches at 100 DAT. The highest number of branches per plant was from Indra which was consistent with NS 632 followed by California Wonder and Sagar. At 100 DAT, the highest (12.62) number of secondary branches per plant was from 250 kg N/ha and the lowest (11.81) was recorded from 150 kg N/ha through chemical fertilizer.

There was significant difference among the varieties on Days to first flowering of the crop. California Wonder took longer time (35 DAT) than Indra (22.66 DAT) for flower initiation. The highest value was recorded from 200 kg N/ha through FYM followed by 250 kg N/ha through chemical fertilizer and 150 kg N/ha through chemical fertilizer (26.167 DAT) and the lowest value was from 200 kg N/ha (25.16 DAT). The varieties

were significantly different in Days to fifty percent flowering. California Wonder took longer time (54.75 DAT) followed by Sagar (43.83 DAT) and Indra (41 DAT). Sagar and Indra were at par while NS 632 took the shortest time (38.5 DAT). The highest value was recorded from 250 kg N/ha through chemical fertilizer (46.08 DAT) and the lowest value was from 150 kg N/ha through chemical fertilizer (43.16 DAT).

The highest (87.59 g) Fruit weight was from Indra followed by NS 632 and Sagar but the lowest (79.93 g) was from California wonder. The highest (85.28 g) fruit weight was from 250 kg N/ha through chemical fertilizer followed by 200 kg N/ha through chemical fertilizer. Application of 200 kg N/ha through FYM was at par with 200 kg N/ha through chemical fertilizer. The lowest (81.6 g) fruit weight was from 150 Kg N/ha through chemical fertilizer.

The highest Number of fruit per plant (9.26) was recorded from NS 632 and it was at par with Indra, but the lowest value (6.30) was from Sagar, which was at par with California Wonder. The highest Number of fruits / plant (8.58) was recorded from the application of 250 kg N/ha through chemical fertilizer followed

by 200 kg N/ha and 150 kg N/ha through chemical fertilizer. The lowest Number of fruits/plant (7.24) was recorded from the application of 200 kg N/ha through FYM.

The highest Fruit yield (39.45 t/ha) was recorded from Indra which was at par with NS 632 and the lowest value (25.99 t/ha) was from Sagar which was at par with the California wonder. The highest Fruit yield (36.69 t/ha) was recorded from the application of 250 kg N/ha through chemical fertilizer followed by 200 kg N/ha through chemical fertilizers and the lowest Fruit yield (30.5 t/ha) was obtained from 200 kg N/ha through FYM which was at par with the 150 kg N/ha through chemical fertilizer.

Interaction effects of varieties and nitrogen levels on the Fruit weight and Number of fruits per plant

Interaction effects of varieties and nitrogen levels on the Fruit weight and the Number of fruit per plant were non-significant (Table 7 and 8).

Discussion

Plant height is a desirable character which contributes to the increment of plant canopy and biomass. The variations in plant height among varieties were most probably being attributed to their inherited traits or the growing environment. The hybrid varieties gained more height as compared to other open pollinated varieties (Nagre et al., 2013; Shrestha et al., 2013). With the higher rates of nitrogen the plant height was recorded taller than the application of lower level of nitrogen. A higher dose of nitrogen increased plant height (Bar et al., 2001; Bowen & Frey, 2002; Pervez et al., 2004). Nitrogen increases the vegetative growth of the plants (Baloch, Chachar, & Tareen, 2008); thus, it increased with the increment in nitrogen level.

Number of leaves per plant influences the fruit production. The more the vegetative growth, greater will be the process of photosynthesis, ultimately resulting into increased number of fruits per plant. The variations in leaf number among varieties may be due to the genetic makeup of the varieties or due to the agro-ecological variations in which the varieties were evaluated. Higher vegetative growth and more number of leaves per plant in hybrid Indra was also recorded by Nagre et al. (2013). Nitrogen fertilization increased number of leaves that was in agreement with the findings of Ayodele (2002) and Boroujerdnia & Alemzadeh (2007). The results were also to some extent in agreement with the findings of Roy Chaudhury, Chatterjee & Mitra (1995) that maximum number of leaves per plant was obtained from higher dose of nitrogen applications.

Hybrid varieties produced higher number of branches per plant. Higher vegetative growth was recorded from Indra variety than others, which was consistent findings by several researchers (Nagre et al., 2013 and Swamy et al., 2014). Generally, the differences in branching of pepper plants might be due to genetic variations existed or due to favorable influence of organic and inorganic nutrients present in the soils or the growing environment. Khan et al. (2010) reported that number of branches increased with the increasing nitrogen rate. Nitrogen has a significant effect on number of branches per plant as it activated vegetative growth.

Earliness or lateness in the days to 50% flowering might have been due to their inherited characters, early acclimatization to the growing area to enhance

their growth and developments and/ or due to the transplanting disturbance. Hybrid variety showed early bearing habit as compared to other open pollinated varieties. Baker (1989) reported that the hybrid Indra had comparatively early flower initiation and early first harvest. There was an early flowering from the low nitrogen application rate as compared to high nitrogen rates. Shrivastava (1996) reported that 50% flowering was delayed with higher dose of nitrogen.

The variations in fruit weight, length and diameter of sweet pepper could be due to the difference in inherited characteristics of varieties and or due to environmental conditions of the growing areas (Sundaram, 1992; Aruna & Sudagar, 2010). Higher values of fruit length, width and wall thickness contributed to maximum average fruit weight in the hybrids Indra and NS-280 as reported by Swami (2015). Fruit size is increased with the increasing nitrogen rates. Qawasmi et al. (1999) also reported that fruit size was smaller when no N was applied. Bowen & Frey (2002) reported that large fruit size was the main factor contributing to higher fruit yield and also reported that increasing the rate of nitrogen fertilizers increased the average fruit weight and volume of pepper.

The hybrid varieties produced more number of fruits than traditional OP varieties. As the number of primary, secondary and tertiary branches increase, there could be a possibility of increasing the number of fruit producing buds. That the fruit production of hybrid varieties was more than the conventional varieties was also supported by Arya (1999) as hybrid varieties had higher potential in terms of yield, uniformity, early maturity, tolerance to biotic and abiotic stresses and better quality.

Availability of soil N is the most important factor in limiting the yield in organic systems, though mineral N levels varied by crop, farming system and the amount and source of N fertilization (Poudel et al., 2002).

Lower yields of sweet pepper with organic manures application may have been associated with the less readily available nutrients as nutrient cycling processes (Harris et al., 1994; Reider et al., 2000) and slower release rates of organic materials (Liebhardt et al., 1989; MacRae et al., 1993). Russo and Taylor (2006) reported that bell pepper yield in the transition to organic production was lower than in the conventional production system.

Roychaudhury et al. (1995) reported that the number of fruit per plant increased with increasing nitrogen applications. Variation in yield between varieties is due to the genetic variations between the varieties. The increase in total fruit yield could be due to variation in plant height, as well as formation of more primary, secondary and tertiary branches per plant that increased potential of fruit bearing buds and also leaf area that maximized photosynthetic capacity and assimilate partitioning to the fruits. Fertilizer is one of the major factors of crop production and nitrogen is a nutrient essential for good growth and development of plants (Khan et al. 2010). Khan et al. (2010) also reported that optimum dose of N fertilizer increased proper growth and development and maximized the yield of sweet pepper. Sharma & Peshin (1994) also stated about the promotive effects of nitrogen application on fruit yield of capsicum.

Conclusion

The yield and yield attributing characters differed with the varieties. The cultivation of hybrids over the OP was very effective. The hybrids Indra and NS 632 were superior to Sagar and California Wonder varieties. Maximum weight (87.59 g) of Capsicum fruits was obtained from Indra with application of 250 kg N/ha through chemical fertilizer. Maximum number of fruits per plant (9.25) was recorded from NS 632. Maximum total yield (39.45 t/ha) was from Indra. More yield (36.69 t/ha) was recorded from 250 kg N/ha through chemical fertilizer and lower yield (30.50 t/ha) from 200 kg N/ha through FYM.

The productivity of pepper is highly responsive to N fertilizer. The source and level of nitrogen is very important in determining the yield and quality of capsicum. Application of FYM alone produced lower yield as compared to chemical source of nitrogen. It might be due to slower release of nutrients from FYM. The capacity of producing yield varies with the variety, level of nutrients and soil types. Thus, it can be concluded that hybrid Capsicum cultivation with optimum dose of fertilizer in autumn will be profitable in Chitwan.
